The **Microsoft Excel solver add-in** is one of the features that makes creating engineering and financial models in a spreadsheet a powerful tool. To be called "solver" doesn't do it justice, though, because it is really a powerful **optimization** algorithm. The tool was developed by Frontline Systems, Inc. (Solver.com) ; offer a great deal of information on their website, including products that extend upon the free Excel solver add in. **This article provides a couple of examples how to use the Excel solver and call it using a VBA macro.**

Note: You do not need to download the add in. If you don't see it as one of the menu items in the Tools menu (in Excel), then you need to go to Tools > Add-Ins... and check the box next to "Add In".

Excel Solver Examples

Example 1: "Finding a Local Minimum Using the Excel Solver"

< [Download Excel Solver Example 1 \(.xls\)](#) >

Our first example is going to be very basic, but it will introduce common terms used in optimization, such as **objective function**, **design variables**, and **constraints**. Let's say we have the following equation, and we want to find the value of x that **minimizes** f subject to $-1 \leq x \leq 5$.

$$f = x^2 - x + 2$$

Our **objective function** is the value that we are going to minimize (f). The **design variables** are the variables that we are going to allow the Solver to change (just x in this example). We have two **constraints**: $-1 \leq x \leq 5$

A convenient way of setting up this problem in Excel is to make a clear distinction between the objective, design variables, and constraints. A screenshot of the example problem is shown below, including the graph of the function so that you can see that **the answer should be somewhere between 0 and 2**. We need to choose a **starting value** for x , so let's choose $x = 1$ because that is the average number of times Excel crashes on n

week.

Figure 1: Screenshot of example problem 1.

Cell B11 (The Objective Function): $=B15^2-B15+2$

To use the Excel solver add in (Tools > Solver ...), we choose our objective function, cell B11, to be the "Target Cell" and choose the "Min" option (Figure 2 below). Our only design variable is x , so the only cell we are changing is B15. After adding the two constraints, we click on the Solve button and we find our answer ($x=0.5$).

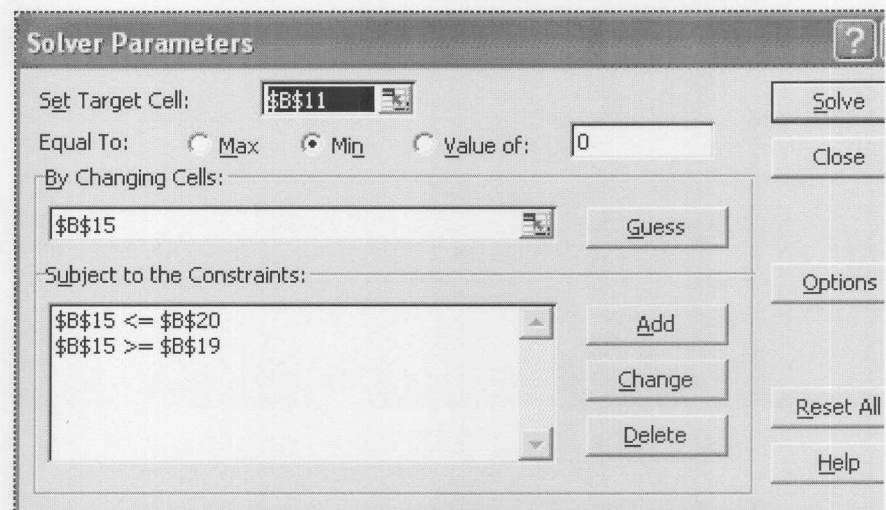

Figure 2: Screenshot of the solver add in dialog box for sample problem 1.

Example 2: "Solving a System of Non-Linear Equations"

< [Download Excel Solver Example 2 \(.xls\)](#) >

In this next practice problem, the solver is used to find values for the angles (θ_2 and θ_3) in the following system of equations.

$$f_1 = r_2 \cos \theta_2 + r_3 \cos \theta_3 - r_4 = 0$$

$$f_2 = r_2 \sin \theta_2 + r_3 \sin \theta_3 = 0$$

Known: $r_2 = 2$, $r_3 = 3$, $r_4 = 4$

Unknown: θ_2 , θ_3

Notice that these equations are in **implicit** form (equal to zero). To solve the system, we will create an objective function that when **minimized**, drives **both equations to zero**. Minimizing the **sum of the squares** of each equation will accomplish this.

The layout for this problem is shown in the screenshot below. The known variables are called **analysis variables** and will be treated as constants. The unknowns, θ_2 and θ_3 , are the **design variables**. For this example problem, we don't have any constraints.

	A	B	C	D	E	F
9						
10	Analysis Variables (knowns)					
11	r_2	2				
12	r_3	3				
13	r_4	4				
14						
15	Design Variables (unknowns)					
16	θ_2	46.56757 degrees				
17	θ_3	331.0448 degrees				
18						
19	System of Equations					
20	f_1	-6.7E-06				
21	f_2	-4.9E-06				
22						
23	Objective Function					
24	obj	6.92E-11				
25						

$$f_1 = r_2 \cos \theta_2 + r_3 \cos \theta_3 - r_4 = 0$$

$$f_2 = r_2 \sin \theta_2 + r_3 \sin \theta_3 = 0$$

Figure 3: Screenshot of example problem 2.

Is There Only ONE Solution?

The screenshot above shows one solution to the problem, but the solution depends upon the **starting values** that you have chosen for the unknown angles. For example, try using the starting values, $\theta_2 = -30$ degrees, and $\theta_3 = 0$ degrees. **You should get a different solution!** The figure below is an example of a mechanism that can be described using these equations. The second solution is represented by the dashed lines.

Figure 4: Mechanism showing two possible configurations.

This example has demonstrated a very important point having to do with Excel solver and optimization in general. **The solution may depend on starting values.** For optimization problems, this means that the solution may be only a **local** optimum.

Run the Solver Using a VBA Macro

If you need to solve the same system of equations or run an optimization repeatedly a number of times using the same model, it is convenient to create a macro that can be run by pressing a single button. An easy way to set this up is to first **record the steps used to set up and run the solver**. Let's use the problem from Figure 2 above.

To Record a Solver Macro:

- **Step 1:** Start the macro recorder (Tools > Macro > Record New Macro ...).
- **Step 2:** Open the solver dialog box (Tools > Solver ...).
- **Step 3:** Clear any existing solver settings (Press the **Reset All** button).
- **Step 4:** Choose the target cell, design variables, and constraints and press the Solve button. Then select OK to accept the results.
- **Step 5:** Stop the macro recorder (Tools > Macro > Stop Recording ...).
- **Step 6:** Add a button to the worksheet, using a button from the Forms toolbar. (If the Forms toolbar is not displayed, right-click on any toolbar and click on "Forms").
- **Step 7:** Assign the macro you created to the button. (Right-click on the button and choose "Assign Macro ...")

Before the macro will work, a reference to the Solver VBA add-in functions must be added.

Adding the Solver Reference:

- **Step 1:** Edit the macro you just created (Tools > Macro > Macros... (Alt+F8). This will open up Visual Basic. You can also press Alt+F11 to VBA.
- **Step 2:** Add the Solver reference in visual basic (Tools > References. make sure that SOLVER is checked).

The VBA code for the Solver macro that was recorded for Example 2 is below.

```
Sub SolverMacro()  
' Example Solver VBA Macro  
SolverReset  
SolverOk SetCell:="$B$24", _  
    MaxMinVal:=2, _  
    ValueOf:="0", _  
    ByChange:="$B$16:$B$17"  
SolverSolve userFinish:=True  
End Sub
```

To keep the **Solver Results** dialog box from showing up, the **userFinish:=True** option has been added to the **SolverSolve** function. For more help on using the Solver functions in VBA, search for "solver" in the **VBA help** system.
